# CLIENT FLOW

Firstly. User fill two fields are email and password in the form. Then the system will check validation of this form. We have two cases. The first case is false, it means, user information is invalid and user will fill their information again. The last case is true, it means everything is valid and our system will call API to log in the system.

When our system we have two cases again, this is true and false.

      True case: everything is OK and user will be logged in the system.

      False case: Email and password is wrong, System will alert a message to user know that they will fill their information again.
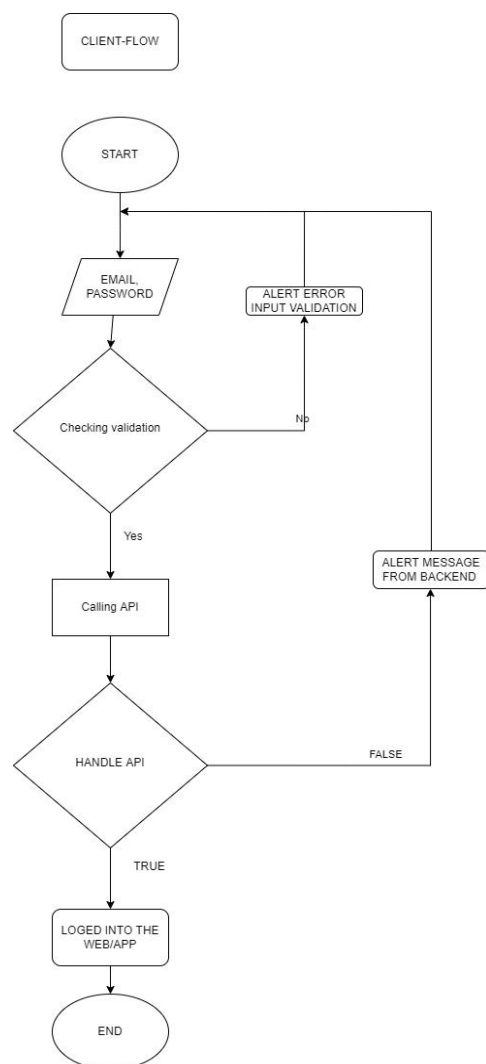

SERVER-FLOW

The firstly. We will check simple email and password, checking its length. Then we check for exiting email. And lastly, we compare password from client with email's password from database.
